8	fig1.jpg	 Figure 8 consists of two panels, (a) and (b). Panel (a) is a line graph showing electrostatic potential (mV) on a logarithmic y-axis (from 10 to 1000) versus distance from surface (x in Angstroms) on a linear x-axis (from 0 to 20). Five curves are shown for different voltages: 1000 mV (black), 200 mV (red), 100 mV (blue), 50 mV (green), and 20 mV (yellow). All curves show a decreasing trend as distance increases. Panel (b) is a line graph showing counterion concentration (mol/L) on a logarithmic y-axis (from 10⁰ to 10⁵) versus distance from surface (x in Angstroms) on a linear x-axis (from 0 to 20). The same five voltage curves are shown, all exhibiting a sharp decrease in concentration as distance increases. A legend in both panels identifies the voltage levels for each color.	Two-panel figure showing X-Y charts. Panel (a) displays electrostatic potential (mV) versus distance from surface (Angstroms) with curves for different voltages: 1000 mV, 200 mV, 100 mV, 50 mV, and 20 mV. Panel (b) shows counterion concentration (mol/L) versus distance from surface (Angstroms) with the same voltage curves. Both charts illustrate how potential and concentration decrease with distance, with a legend indicating voltage levels.
10	fig1.jpg	 <pre> graph TD Start([Set up system current throttle=100% initial hct=0]) --> Init[Initial guess (zero)] Init --> Solve[Solve] Solve --> Converged{converged?} Converged -- no --> LowerThrottle[lower throttle by bisection set to 50%] LowerThrottle --> Solve Converged -- yes --> ApplyPrevious[apply previous converged solution as new initial guess] ApplyPrevious --> Solve Solve --> Throttling{throttling is 100%?} Throttling -- no --> IncreaseThrottle[1. set throttle 2. solve throttle 3. solve throttle 4. set throttle to 100%] IncreaseThrottle --> Solve Throttling -- yes --> Quit1([quit after 1000 iterations or if co-act falls below 1e-5]) Quit1 --> End([Final solution]) </pre>	Flowchart illustrating a system setup and throttle adjustment process. It begins with setting up the system with a current throttle of 100% and an initial hct of 0%. The process involves solving for convergence, adjusting throttle values, and using previous solutions as initial guesses. If convergence is not achieved, the throttle is lowered by bisection. If convergence is achieved, it checks if throttling is 100%. If not, it applies a new throttle to increase boundary conditions. The process includes conditions for quitting after 1000 iterations or if specific thresholds are met. The final solution is reached when throttling is 100%.
11	fig1.jpg	 Figure 11 consists of two panels, (a) and (b). Panel (a) is titled 'Iterations for 1V' and shows throttle (y-axis, 0 to 1) versus N iteration (x-axis, 0 to 20). Three curves are plotted for different values of r: r=1 (black), r=2 (orange), and r=3 (blue). All curves start at a throttle of 1.0 and decrease before increasing towards 1.0. Panel (b) is titled 'Iterations for 10 V' and shows throttle (y-axis, 0 to 1) versus N iteration (x-axis, 0 to 50). The same three curves for r=1, 2, and 3 are shown. In both panels, the curves for higher r values converge to a throttle of 1.0 more rapidly than those for lower r values.	Two-panel figure showing X-Y charts of throttle versus N iteration. Panel (a) is titled "Iterations for 1V" and displays three lines representing different values of r: r=1 (black), r=2 (orange), and r=3 (blue). Panel (b) is titled "Iterations for 10 V" and displays three lines representing different values of r: r=1 (black), r=2 (orange), and r=3 (blue). Both panels show throttle values on the y-axis (from 0 to 1) versus N iteration on the x-axis (from 0 to 20 for panel a, and 0 to 50 for panel b). The throttle values generally increase with iteration, with higher r values showing faster convergence.

			(blue). Panel (b) is titled "Iterations for 10V" and shows three lines for $r=2$ (orange), $r=3$ (blue), and $r=4$ (green). Each line demonstrates the relationship between throttle and iterations, with varying slopes and patterns. Legends in both panels indicate the corresponding r values.
12	fig1.jpg		Graph showing the relationship between surface potential (V) on the x-axis and best r (minimum attempts) on the y-axis. Multiple data series are plotted, including a magenta line representing the fit with the equation $(r = 1 + 3.8 \ln(1 + 0.1V))$, a dashed orange line for log_zero 1D 1.0 M, and a solid black line for trivial 1D 1.0 M. Other series include 2D, 3D, and 1D at various concentrations, marked with different symbols. The graph illustrates how different conditions affect the best r value as surface potential increases.
14	fig1.jpg		Graph showing the relationship between potential (V) on the x-axis and the number of throttling iterations on the y-axis, both on logarithmic scales. Two scaling methods are compared: "log-zero scaling" in orange and "trivial scaling" in black. The graph includes two equations: $(r = 1 + 1.3 \ln(1 + 0.7V))$ and $(r = 1 + 3.8 \ln(1 + 0.1V))$. Data points are marked for 2D (squares) and 3D (crosses) scenarios.

15	fig1.jpg	 The figure contains two side-by-side plots, labeled (a) and (b). Plot (a) shows the electrostatic potential (V) on a logarithmic y-axis (0.00 to 10) against the distance from the electrode (nm) on the x-axis (0 to 4). The curve starts at 10 V at 0 nm and decreases to 0.00 V at 4 nm. Plot (b) shows the counterion concentration (M) on a linear y-axis (0 to 40) against the distance from the electrode (nm) on the x-axis (0 to 4). The curve starts at 40 M at 0 nm and decreases to 0 M at 4 nm.	Two X-Y charts are presented. Chart (a) shows the electrostatic potential (V) on the y-axis, plotted against the distance from the electrode (nm) on the x-axis. The curve indicates a decrease in potential as the distance increases. Chart (b) displays the counterion concentration (M) on the y-axis, also plotted against the distance from the electrode (nm) on the x-axis. The curve shows a decrease in concentration with increasing distance.
